EXPERIMENT

Title

SUM OF NUMBERS AT PRIME FACTORS

Description

Prime factors of a positive integer are the prime numbers that divide that integer exactly.

Given an array arr of n integers and a positive integer num.

Let's suppose prime factorization of num is: $p^a \times q^b \times r^c \times .... \times z^f$,where p,q,r...z are prime numbers.

Sum of numbers in array arr at indices of prime factors of number num is: a x arr[p] + b x arr[q] + c x arr[r] +..... + f x arr[z].

You are given an array arr of size n and a positive integer num. You are required to calculate the sum of numbers in arr as mentioned above, and print the same.

Note:

- If arr is empty, print -1.
- If prime factor of num not found as indices, print 0.

Input Format:

The input consists of three lines:

- The first line contains an integer, i.e. n.
- The second line contains an array arr of length of n.
- The third line contains an integer num

The input will be read from the STDIN by the candidates.

Output Format:

Print the sum that was mentioned in the problem statement.

Example:

Input:

6

11 21 32 45 1 23

6

Output:

77

Explanation:

$6=2^1 \times 3^1$

sum=1*arr[2]+1*arr[3]=1*32+1*45=77

Source Code:

```
def prime_factor_sum(arr, num):
    if not arr:
        return -1

    # Function to get prime factors of num
    def get_prime_factors(n):
        factors = set()
        for i in range(2, n + 1):
            while n % i == 0:
                factors.add(i)
                n //= i
        return factors

    factors = get_prime_factors(num)
    total_sum = sum(arr[f] for f in factors if f < len(arr))

    return total_sum if total_sum > 0 else 0

# Input reading
n = int(input())
arr = list(map(int, input().split()))
num = int(input())
print(prime_factor_sum(arr, num))
```
